

An Image Processing Demonstration Using the Cmpware CMP-DK

Steven A. Guccione Cmpware, Inc.

Multicore Image Processing

- Multicore devices increasingly used for image and video processing
- High performance, low power and high levels of programmability make multicore attractive
- This demo uses the *Cmpware CMP-DK* to:
 - 1. Model a multicore architecture
 - 2. Write software for this architecture
 - 3. Execute compiled code on the model
 - 4. View the results interactively in the IDE

Introduction: Image Morphology

Other Morphology Kernels

The Multicore Architecture

- 3 PowerPC processors
- 'Ring' architecture

- 16k local memory per CPU
 - Image processing code
 - Local data
- 128k shared memory per CPU
 - Shared between adjacent pairs of processors
 - Provides all communication and synchronization

Modeling the Architecture

- Uses existing *Cmpware* models:
 - <u>Processor</u>: PowerPC
 - Network: Ring

- Link: SharedMemory (not used)
- System Memory: Ring
- Pre-configured in 'ppcdemo' Eclipse plugin installable from:

http://www.cmpware.com/ppcdemo/

The 'ppcdemo' Preferences

The Processing Node

Addressing Shared Memory

- Each node 'sees' two shared memories
- 'East' shared memory at address 0x40000
- 'West' shared memory at address 0x80000

The Cmpware CMP-DK IDE

- Multicore simulation model 'plugs in' to the *Cmpware* IDE
- Dynamically customizes the displays for this multicore architecture
- Standard compiled *PowerPC* executables run on the simulation model
- A debugger-like interface displays system information, including performance data

Cmpware CMP-DK IDE

Executing the Application

- Uses existing 'C' compilers (Gnu)
- Communication through shared memory
 - Requires use of same memory map / addresses as hardware simulation model
 - Memory mapped *channels* also available
- *Image.c* compiled for different filters
- ImageO.c initiates execution
- Image data pre-loaded into processor (0,0) shared memory from *Flower256.elf*

Building the 'C' Code

The Inner Loops

```
/* Wait until image data available */
while (*(image+(HEIGHT*WIDTH)) == 0)
   ; // wait
/* Process the image */
for (y=0; y<HEIGHT; y++)</pre>
   for (x=0; x<WIDTH; x++)
      dest[(y*WIDTH)+x] = filter(x, y, KERNEL);
/* Synchronize */
/* (tell the next processor that the image is ready) */
*(dest + (HEIGHT*WIDTH)) = 1;
```

The P(0,0) Original Image

The P(1,0) Smoothed Image

The P(2,0) Edge-detected Image

Performance

- Processor (0,0) only loads original image
- Two processors processing images
 - Smoothing with 3 x 3 kernel
 - Edge enhancement with 3 x 3 Laplacian filter
- **100M** cycles total execution

Problem: edge detection waits for entire image smoothing before beginning

==> 50% processor utilization (even / odd pattern)

Improving Performance

- Performance limited by synchronization
- No need to wait for entire image
- **Plan:** synchronize at every line of pixels
 - Somewhat more complex code
 - Executes in **50M** cycles
 - 2x performance of original code
 - Approaches 100% processor efficiency
 - Performance extends to higher numbers of processors

The Improved Inner Loops

```
/* Process the image */
for (y=0; y<HEIGHT; y++) {
    while (*imageLineReady < (v+3))</pre>
        ; // wait for data to be ready
      /* Process line of pixels */
      for (x=0; x<WIDTH; x++)</pre>
         dest[(y*WIDTH)+x] = filter(x, y, KERNEL);
      /* Tell the next processor we finished line <y> */
      *currentImageLine = v;
   } /* end for(y) */
```

Parallelism

- Lots of parallelism available in this algorithm
- Every stage depends on 3 available lines
- Each pixel can be computed in parallel
- Potential for hundreds of processing cores
- Real-time requirements suggest far fewer
 - 1k x 1k video at 30 fps = 30M pixels / sec
 - At 100 ops per pixel, 3B ops / sec
 - 10 cores at 300 Mhz (approx.)

A Note on Synchronization

- Proper synchronization very important
- Shared Memory generally requires atomic 'test-and-set' operation
- This Image Processing algorithm:
 - Only sends data in one direction
 - One reader, one writer
 - Can use a simpler synchronization scheme
- Cmpware 'channels' suitable for more general-purpose synchronization

Cmpware CMP-DK

- Model complex multicore processors
- Edit, compile, execute *and* debug multicore software

... all in the same friendly environment

- Develop multicore code faster
- Evaluate performance more quickly
- Faster feedback for algorithm partitioning
- Evaluate more alternatives in less time
- Produce more reliable multicore software

Installing the Demo

• Available as an *Eclipse* plugin at the Eclipse update site:

http://www.cmpware.com/ppcdemo/

• Other files avaliable at:

http://www.cmpware.com/ppcdemo/Ppcfiles.zip

• For more information on how to install an *Eclipse* plugin from an update site, see:

http://www.cmpware.com/demo/DemoInstall_2.2.1.pdf
